This book is not only a basic resource for the reference of practicing engineering engineers, but also an important tool for academics and teachers of architecture. 1. Introduction [sec1] ===== Development of construction materials has a significant effect on the progress of the construction industry, and on the economy as a whole. The construction industry has a very high demand for construction materials, such as concrete, steel, and bricks. In order to produce these materials, the use of traditional raw materials is limited, and the amount of resources required to produce these materials is becoming increasingly scarce. Since the consumption of traditional construction materials is growing more rapidly than the production of these materials, the use of secondary materials is on the rise. In order to utilize secondary resources more efficiently, in the next century, the construction industry must not only utilize resources more efficiently, but also replace traditional resources with secondary resources. Sustainable development is an urgent requirement of the construction industry. To meet these requirements, developing eco-materials is becoming increasingly important. Concrete is a typical construction material, and is widely used in different construction processes. The application of concrete makes use of concrete technology, which includes concrete preparation and consolidation (casting, mixing, and construction), reinforcement and strengthening (binder application, rebar application, and steel fiber application), and finishing (pouring, finishing, and curing). Concrete is one of the most common construction materials, and is widely used in the construction of different structures such as buildings, bridges, tunnels, and airports. The effects of concrete technology on the quality and durability of the construction are widely recognized. Concrete is the most popular construction material, but the use of traditional concrete has become more limited because it consumes more resources and has a high environmental impact. In recent years, concrete has been subjected to the same standards as steel and steel components, such as the design and use of prestressing steel. The recent change in environmental regulations requires the use of other secondary resources, such as recycled cement, fly ash, and metakaolin. Recycled steel has become increasingly popular because it does not require the use of steel resources, and has a lower environmental impact. Its application has increased significantly, and recycled steel has become an important part of the construction industry. However, the application of recycled steel in the construction industry has not met the expectations of the public. As the quality of recycled steel is not as good as that of ordinary steel, the use of recycled steel cannot replace conventional steel. However, the use of 82157476af
